

CLAIMS

1. Method of transmitting data in a telecommunications system including a transmitter and a receiver intended to be connected together via an intermediate device including control means intended on the one hand to provide management of at least one signalling port able to receive connection authorisation requests and to deliver such authorisations, and on the other hand to provide management of at least one listening port to which the transmitter and receiver are able to be connected after having been authorised for this by the intermediate device, a method including:

. a step for configuring the intermediate device in a so-called default access authorisation mode, in which the said intermediate device is deemed to authorise any connection to the said listening port, and

. a step for connecting the transmitter and receiver to the said listening port.

2. Method according to claim 1, including a prior step of transmission, by the intermediate device, of the said address peculiar to the listening port to which the transmitter is intended to be connected.

3. Telecommunication system including a transmitter and receiver intended to be connected together via an intermediate device including control means intended to provide management of at least one signalling port able on the one hand to receive connection authorisation requests and to deliver such authorisations, and on the

other hand to provide management of at least one listening port to which the transmitter and receiver are able to be connected after having been authorised for this by the intermediate device, a system in which the intermediate device includes means of configuring in a so-called default access mode, in which the said intermediate device is deemed to authorise any connection to the said listening port, the transmitter also including means for storing an address peculiar to the listening port to which the said transmitter is intended to be connected.

4. Telecommunication system according to claim 3, in which the intermediate device includes means for transmitting the said address peculiar to the listening port to which the transmitter is intended to be connected.

5. Server able to fulfil the functions of an intermediate device included in a telecommunication system according to one of claims 3 or 4.
